## Abstract

**Background:** The age-dependent sporadic form of PD is characterized by the degeneration of dopaminergic (DA) neurons in the Substantia Nigra (SN), gliosis, and vascular changes. Vascular changes may contribute to the onset of the disease and exacerbate the neurodegenerative process, as some vascular changes occur before the onset of neuronal loss. To demonstrate the anti-neuroinflammatory efficacy of a new compound, a water-soluble form of dihydroquercetin (DHQ-WF), we studied the structural changes of microcirculatory vasculature, astroglial GFAP, and vascular endothelial growth factor -A (VEGF-A) mRNA expression in the SN of young and old rats after unilateral nigral treatment by lipopolysaccharide (LPS) and oral administration of DHQ-WF.

**Materials and methods:** The experiments were performed on 18 young (8 weeks - 10 weeks old; 250 g - 320 g) and 18 old (18 months - 19 months old; 390 g - 450 g) male Vistar rats. Young and adult rats from the experimental groups were stereotactically injected with 2  $\mu$ L LPS solution (LPS from *Escherichia coli*; 0,01  $\mu$ L/mL) into one side of the SN. Control young and old rats were similarly injected with 2  $\mu$ L sterile saline. Half of the animals in both the control and experimental groups (6 animals in each group) received a 2 ml solution containing DHQ-WF at a concentration of 3 mg/ml orally every day. After 8 weeks, brains were harvested and serial cryostat sections were prepared for histochemical (FITC-labeled tomato lectin), immunohistochemical (anti-GFAP Antibody, Cy3 Conjugate) staining, and real-time PCR (mRNA VEGF-A).

**Results:** Eight weeks after LPS injection into the SN, a significant excess of areas occupied by cell bodies and processes of astroglial cells, the density of microcirculatory vessels, and mRNA VEGF-A expression was observed in old animals compared to control old animals and young LPS-treated rats. Oral administration of DHQ-WF to LPS-treated rats resulted in a significant reduction of these parameters in old animals.

**Conclusion:** Injection of LPS into rat SN induces neuroinflammation and vascular angiogenesis, maximally expressed in old animals. Administration of DHQ-WF for 8 weeks significantly reduces these LPS-induced changes. DHQ-WF may be an effective treatment for reducing the effects of neuroinflammation in the aging brain.

## Introduction

Aging is a major risk factor for several neurodegenerative diseases [1], including Parkinson's disease (PD) [2], which is characterized by progressive degeneration of dopaminergic (DA) neurons in the substantia nigra compacta (SNc) [3]. The neurodegenerative process is preceded by chronic neuroinflammation characterized by gliosis [4] as well as vascular changes, disruption of the Blood-Brain Barrier (BBB), and abnormalities in cerebral blood flow [5,6]. Vascular

alterations can contribute to disease onset and aggravate the neurodegenerative process as some vascular changes already occur before the onset of neuronal loss or behavioral deficits in animal models of the respective disease [7,8]. Previous studies have reported changes in SN vascularization in PD patients and animal models of PD [9,10]. Similarly, aging is known to cause changes in angiogenesis in the brain and other tissues [11].

Vascular Endothelial Growth Factor (VEGF) is a key

**Keywords:** Neuroinflammation; Astroglia; Microvasculature; Ageing; Water-soluble form of dihydroquercetin

mediator of angiogenesis and vascular permeability [12,13], and is thought to be involved in aging-induced vascular changes observed in PD and PD animal models [10,14].

In recent years, researchers have increasingly focused on the potential use of plant polyphenolic secondary metabolites as antioxidant and anti-inflammatory agents, particularly taxifolin (3, 5, 7, 3, 3, and 4-pentahydroxy flavanone), also known as Dihydroquercetin (DHQ). DHQ has been confirmed to exhibit various pharmacological activities, including anti-inflammation and regulation of oxidative stress effects [15]. An *in vitro* study has shown that taxifolin is able to inhibit LPS-induced activation of the mRNA and protein levels of inducible nitric oxide synthase (iNOS) and VEGF [16]. The water-soluble form of dihydroquercetin (DHQ-WF) demonstrated an even more pronounced neuroprotective effect under *in vitro* conditions [17].

However, there is no data on the protective properties of the DHQ-WF and its mechanisms of action in PD models in animals of different ages. In this study, we examined VEGF expression, vascular remodeling, and astroglia activation in the SN of young and old rats in response to stereotactic injection of lipopolysaccharide (LPS) and subsequent oral administration of DHQ-WF.

## Methods

### Experimental design

Experiments were performed on 18 young (8 weeks - 10 weeks old; 250 g - 320 g) and 18 old (18 months - 19 months old; 390 g - 450 g) Vistar male rats. All animal procedures were performed in accordance with the Rules of Laboratory Practice in Russia (Order No. 267 of the Ministry of Health of the Russian Federation; 19 June 2003). The experimental protocol fulfilled the requirements of the EU Directive 2010/63/EU and was approved by the Bioethics Committees of Izhevsk State Medical Academy (Protocol № 634, 11.12.2008). Using a stereotaxic device, we injected the 2 µl LPS solution (LPS from *Escherichia coli* O55:B5, Sigma-Aldrich, USA, L2880; 0.01 µl/ml) into the SN of young ( $n = 12$ ) and old ( $n = 12$ ) rats (experimental groups) and 2 µl of sterile saline into the SN of control young ( $n = 6$ ) and old ( $n = 6$ ) rats. Half of the animals from the experimental groups (consisting of 6 animals from each age group) were given 2 ml of DHQ-WF solution (Advanced Technologies Ltd., Russia) 3 mg/ml orally daily. After 8 weeks, animals were euthanized, brains were sampled and serial cryostat sections (14 µm) were obtained for histochemical (FITC-labelled tomato lectin) and immunohistochemical (anti-GFAP Antibody, Cy3 conjugate) staining, and real-time PCR analysis of SN-containing fragments isolated from a ventral midbrain section on the LPS administration side (mRNA VEGF-A).

### Histochemistry and immunohistochemistry

Histochemical staining of vascular endothelium was

performed on frozen sections incubated with FITC-conjugated *Lycopersicon esculentum* (tomato) lectin (1:500, Sigma-Aldrich, USA; L0401).

Immunohistochemical staining was performed using antibodies to GFAP conjugated to Cy3 (1: 500, Sigma-Aldrich, USA, MAB3402C3). The study was performed in a Nikon Eclipse E200 fluorescent microscope equipped with a digital camera MicroPublisher 3.3. Isolectin-positive vessels and immunopositive cell bodies and processes were quantified in 8 standard rectangular regions (620 x 480 mm) encompassing the SN of at least six brain sections per animal. Digitized images were enhanced for contrast to differentiate positive structures from background, and a thresholding scheme was implemented to measure immunoreactive areas as a percentage of the standard rectangular area using Image-Pro Insight 8.0 (Media Cybernetics, USA). Microvessels not larger than 10 µm in diameter, including capillaries and venules, were specifically selected for morphometric analysis. Quantitative analysis of vascular remodeling was performed using AngioTool [18].

### RNA extraction and real-time quantitative reverse transcriptase PCR

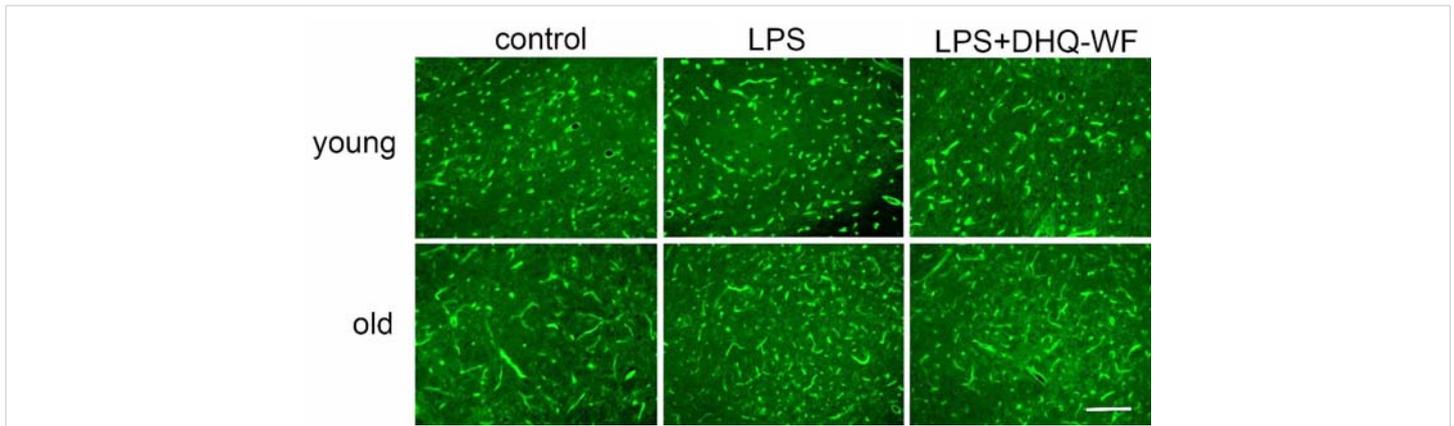

Total RNA from the ventral midbrain slices was extracted with Trizol (Invitrogen, Paisley, UK) according to the manufacturer's instructions. Total RNA (2 mg) was reverse transcribed to cDNA with deoxyribonucleotide triphosphates, random primers, and Moloney murine leukemia virus reverse transcriptase (200 U; Invitrogen). Real-time PCR was used to examine relative levels of VEGF-A mRNA. VEGF-A primers sequences were: forward GCACTGGACCCTGGCTTTAC, reverse CCACCAGGGTCTCAATCGGA. b-Actin was used to normalize the number of cDNA samples (forward TCGTG CGTGACATTAAAGAG, reverse TGCCACAGGATTCC ATACC). Experiments were performed with a CFX96 Touch Real-Time PCR Detection System (Bio-Rad). The comparative Ct (threshold cycle) method was used to examine the relative mRNA expression

### Statistical analysis

Statistical analysis was performed using Statistica 10.0 software (SPSS Inc., Chicago, IL, USA). Data were expressed as a percentage relative to young control, the arithmetic mean of which was taken as 100%. Result distributions were tested for normality using the Shapiro-Wilk W test. One-way analysis of variance (ANOVA) with Tukey's post-hoc test for multiple comparisons between study groups. Results were considered statistically significant when  $p < 0.05$ .

## Results

Comparative analysis of microvessel morphology labeled with tomato lectin (Figure 1) and VEGF mRNA expression in the SN of rats under normal and experimental conditions showed significant differences between animals of different ages.

**Figure 1:** Photomicrographs of nigral microvessels from young and aged rats marked with FITC-conjugated tomato lectin 8 weeks after administration of sterile saline (control), lipopolysaccharide (LPS), and lipopolysaccharide with simultaneous oral administration of a water-soluble form of dihydroquercetin (LPS+DHQ-WF). Line length = 100  $\mu$ m.

**Table 1:** VEGF mRNA expression and morphometric parameters of nigral vessels and astroglia in control and experimental young and old rats.

Morphometric parameters and mRNA expression	Age	Investigated groups of rats			p-value LPS/ control	p-value LPS/ LPS+DHQ-WF
		Control	LPS	LPS+DHQ-WF		
Vessel length	Young	100.0 $\pm$ 18.8	110.5 $\pm$ 12.6	112.7 $\pm$ 13.6	0.58	0.46
	Old	177.6 $\pm$ 23.6	144.9 $\pm$ 19.0	133.0 $\pm$ 18.3	0.026	0.59
Number of vessels	Young	100.0 $\pm$ 18.8	116.5 $\pm$ 12.6	112.7 $\pm$ 13.6	0.58	0.46
	Old	77.6 $\pm$ 13.6	164.9 $\pm$ 17.0	139.0 $\pm$ 18.3	0.026	0.59
VEGF mRNA	Young	100.0 $\pm$ 24.9	128.0 $\pm$ 27.0	119.7 $\pm$ 24.9	0.17	0.15
	Old	73.4 $\pm$ 18.4	196.0 $\pm$ 27.9	141.3 $\pm$ 23.7	0.00017	0.00019
Area of GFAP-immunopositive cells	Young	100.0 $\pm$ 14.8	141.4 $\pm$ 27.7	121.7 $\pm$ 20.6	0.022	0.29
	Old	139.1 $\pm$ 23.1	216.8 $\pm$ 38.1	146.3 $\pm$ 28.4	0.017	0.043

Data are presented as percentages relative to young controls, whose values were taken as 100%.

Thus, the mean vessel length in old control animals, counted on a standardized plot, exceeded this index in young individuals of the control group by 77.6% ( $p < 0.05$ ) (Table 1), but the number of microvessels was lower by 22.6% ( $p < 0.05$ ). Eight weeks after a single injection of LPS into the SN, young rats showed a slight trend toward an increase in mean vessel length in this region compared with the corresponding control. At the same time, significant vascular changes were observed in old animals after intranigral injection of LPS. There was a significant 87.3% ( $p < 0.001$ ) increase in vessel number and by 32.8% ( $p < 0.05$ ) decrease in mean vessel length compared to age-matched control animals.

Administration of DHQ-WF for 8 weeks to aged LPS-treated animals resulted in a significant 25% ( $p < 0.05$ ) decrease in vessel density and a non-significant decrease in vessel length.

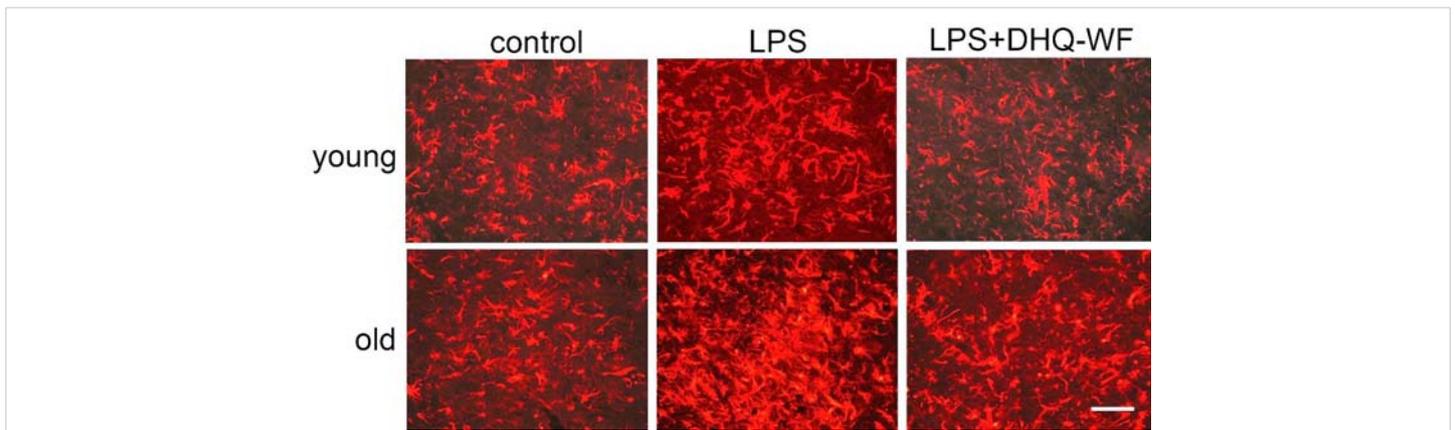

The levels of VEGF mRNA in the old control rats were significantly lower than in the young control rats (by 26.6%;  $p < 0.05$ ). LPS treatment induced an increase in VEGF mRNA expression that was significant only in old rats in comparison to age-matched controls (by 122.6%;  $p < 0.001$ ). Oral administration of DHQ-WF for 8 weeks to aged animals after LPS treatment significantly reduced VEGF mRNA expression by 54.7% ( $p < 0.01$ ) compared with LPS-treated rats, although it did not reach the levels observed in control animals of similar age. No significant changes were observed in young

animals under similar experimental conditions. The area occupied by GFAP-immunopositive bodies and processes in old animals was significantly higher than in young animals at 39.1% ( $p < 0.05$ ) (Figure 2).

Injection of LPS into the SN resulted in an excess of GFAP-immunopositive astroglial area in both age groups: by 41.4% ( $p < 0.05$ ) in young and by 77.7% ( $p < 0.01$ ) in old compared to age-matched controls. Oral administration of DHQ-WF reduced the cell area of astrocytes in both young (by 19.7%;  $p < 0.05$ ) and old LPS-treated animals (by 70.5%;  $p < 0.01$ ).

## Discussion

Analysis of microcirculatory morphology and GFAP expression in the SN of animals of different ages revealed significant age-related differences both in control and after a single injection of LPS, which is known to induce neuroinflammation [19,20]. Importantly, in old rats, even under normal physiological conditions, we observed signs of neuroinflammation in the SN: astrogliosis, as evidenced by a significant excess of areas occupied by GFAP-immunopositive cell bodies and processes, decreased density of microcirculatory vessels with their extended length, indicating an increase in their tortuosity compared to young animals. Such low-level age-related neuroinflammation has previously been referred to as “neuroinflammaging” [21]. This is consistent with observations of similar vascular changes in

**Figure 2:** Photomicrographs of GFAP-immunopositive bodies and processes from young and aged rats labeled 8 weeks after administration of sterile saline (control), lipopolysaccharide (LPS), and lipopolysaccharide with simultaneous oral administration of a water-soluble form of dehydroquercetin (LPS+DHQ-WF). Line length = 80  $\mu$ m.

several regions of the aged brain in both humans and animals. [22- 28]. It was previously shown that the tortuosity index of cerebral collateral vessels in mice increased significantly with increasing relative resistance to blood flow [29]. The observed vascular changes, indicative of decreased mean blood flow velocity in the SN, may underlie the dysfunction of the Dopaminergic (DA) system, which is altered with normal aging [30]. Perfusion deficits have also been observed before the onset of clinical symptoms in other neurodegenerative disorders, which suggests that the deficits contribute to the pathogenesis of the disease [31].

The reduced expression of VEGF mRNA in the SN of the aged control rats compared to the relatively young control animals that were detected in our study may be indicative of a low level of angiogenesis in the SN of the aged rats. The results obtained are consistent with previous data suggesting that the mechanism responsible for impaired angiogenesis in aged animals is related to decreased VEGF expression [11,32].

It is possible that the observed changes in microvessels and astroglia during normal aging may contribute to the “sensitivity” of the age-related central nervous system to the action of additional pro-inflammatory factors. Indeed, we found that a single injection of LPS significantly increased blood microvessel density and VEGF mRNA expression in the SN of old, but not young, animals.

Administration of LPS into the SN-induced angiogenesis as evidenced by an increase in the number of microvessels. Our observation of LPS-induced angiogenesis is consistent with data that hypoxia or inflammation usually induces angiogenesis in the adult brain [33]. Increased nigral vascularization and VEGF levels after LPS administration may be a consequence of induced neuroinflammation because upregulation of VEGF has been reported in inflammatory processes [31]. Importantly, increased vascularization and upregulation of VEGF levels were observed in the SN of PD patients [14,34] and animal models of PD [10,35,36].

There is disagreement regarding the role of VEGF in the development of neuroinflammation and subsequent Parkinson’s disease. Several studies have shown that VEGF is a highly potent neuroprotective and neurorescue molecule for dopamine (DA) neurons [37]. However, recent studies have revealed that VEGF is also involved in neurodegeneration [31]. Thus, increased levels of VEGF in the Cerebrospinal Fluid (CSF) of PD patients have been suggested to be associated with Blood-Brain Barrier (BBB) dysfunction and neuronal degeneration [5]. It has also been suggested that VEGF has a “Janus face” because it has been shown that at different stages of stroke elevated VEGF levels cause destruction of the Blood-Brain Barrier (BBB) and disturbance of homeostasis or have neuroprotective effects [38].

Examination of GFAP-positive astroglia after nigral administration of LPS showed that it increased in young animals, but to a greater extent in old animals. Astrocytes are the most abundant cell type within the CNS, and they provide structural support, promote the formation of the BBB, and release beneficial factors that maintain brain cell development and homeostasis of the extracellular environment [39]. However, under pathological conditions, astrocytes secrete inflammatory factors, such as VEGF, chemokines, and cytokines; these factors directly or indirectly aggravate brain damage and BBB disruption [40]. Recently, it has been proposed that neuroinflammation induced two different types of reactive astrocytes, which are called toxic A1 astrocytes and neuroprotective A2 reactive astrocytes [41].

This suggests that the activation of astroglia in old animals in response to LPS administration is not only characterized by a greater intensity of astrogliosis but also probably by the formation of A1 cells that produce higher levels of VEGF, which in turn induces angiogenesis.

## Conclusion

Daily oral administration of DHQ-WF for 8 weeks resulted

in a significant reduction of LPS-induced astroglial cell activation, microcirculatory changes and reduced VEGF-A mRNA expression, which was more pronounced in old rats compared to young rats under the same experimental conditions. Such a pronounced 'normalizing' effect of DHQ-WF use allows us to consider it as a potent neuroprotective agent capable of reducing abnormalities in the bloodstream and glial microenvironment that lead to the manifestation of Parkinson's disease.

## Recommendations

The data obtained allow us to hypothesize that low-level neuroinflammation and aberrant regulation of VEGF, leading to a decrease in angiogenesis in old age, form an increased sensitivity of the SN to the action of additional inflammatory factors. This may lead to loss of blood-brain barrier integrity, microvascular leakage, increased neuroinflammation, and activation of a self-perpetuating vicious cycle of SN cell death. However, this hypothesis requires further experimental validation. Furthermore, prospective studies with appropriate power levels should be conducted based on this study to verify the conclusion that DHQ-WH is a promising neuro- and neuroprotective agent.
